Keywords: Dielectrophoresis, DEP, microparticles, polystyrene, chromatography, interdigitated electrodes, microfluidic, separation)

1. Method

Figure 1 shows the $\text{Re}(CM)$ and mobility with respect to the frequency. Since the surface conductance (here: $K_s = 1 \text{ nS}$) is not easily measurable, these curves are assumptions and are used as starting point for process parameters. For constant surface conductance and medium conductivity the $\text{Re}(CM)$ only depends on particle size. The chosen frequency band should include the cross-over frequency of all particles to generate nDEP and pDEP.

2. Device Fabrication

2.1. PDMS device

The fabrication of PDMS microfluidic devices (soft lithography) is a well know process, which was described in literature before [1,2]. A SU8-3050 master mold was produced using a laser printed mask (25.000 dpi KOENEN GmbH, Germany, Figure 2 b) and standard photolithography techniques. Afterwards, the PDMS channel can be made by pouring well mixed and degassed PDMS (10:1, base:curing agent, Sylgard 184 Dow corning) onto the master mold. After curing the PDMS at 80 °C for 1 h in a convection oven, the polymer can be cut into pieces as desired using a scalpel. Inlet and outlet, both having an inner diameter of 1.5 mm, were punched using biopsy punches (Rapid-Core, World Precision Instruments, Inc.).

2.2. Electrodes

The electrodes were fabricated using physical vapor deposition of first chrome as adhesion layer and second gold as final layer. As substrate 100 mm borosilicate glass wafer were used. Afterwards, using a chrome mask (100.000 dpi bvm.maskshop, Germany), positive photoresist and followed by a wet etching process, the final electrodes were obtained. These electrodes had a width of 100 μm and an identical gap width. To connect the amplifier to the flow cell contact pins were soldered onto the electrode. The full electrode chip has length of 58 mm and a width of 26 mm (Figure 2 a).

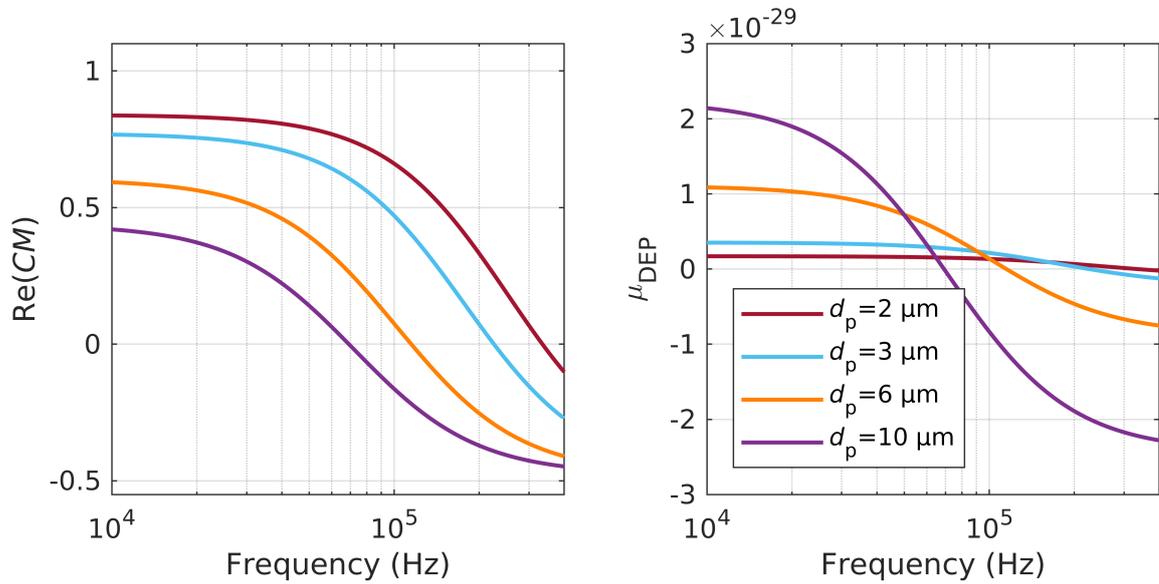

Figure 1. Real part of Clausius-Mossotti factor and dielectrophoretic mobility over frequency of the electric field of polystyrene particles ($d_p = 2 \mu\text{m}$, $3 \mu\text{m}$ and $6 \mu\text{m}$). Particles suspended in DI water as surrounding medium, with $\sigma_m = 1.2 \mu\text{S cm}^{-1}$ and $\epsilon_m = 78.5$).

26 3. Post-processing

27 A segmentation algorithm was used to extract the fluorescence intensity of each colour of
28 fluorescence into different images[3]. Afterwards the intensity of each image was calculated and
29 a moving average was applied to reduce the level of noise of the measured intensities. Finally, the
30 background signal was subtracted for each colour to eliminate scattered light and permanently adhered
31 particles from the data. Since all measurements produce slightly different maximum values and each
32 particle class has a different fluorescence intensity per particle, the Data was normalized by the
33 maximum intensity value of each experiment.

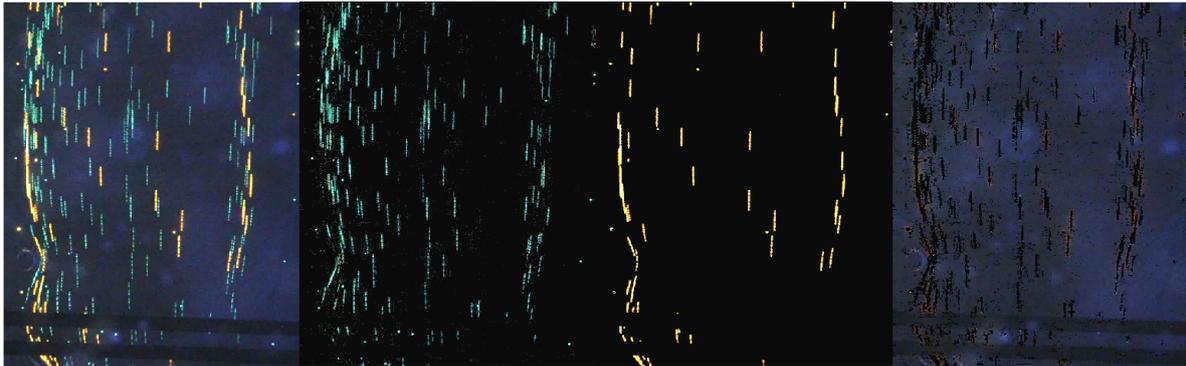

Figure 3. Result of the segmentation process. Original Image, particle typ 1, particle type 2 and background (f.l.t.r.)

34 4. Further experimental results

35 4.1. Full set of intensity profiles

36 4.1.1. Separation of 6 and 3 μm particles

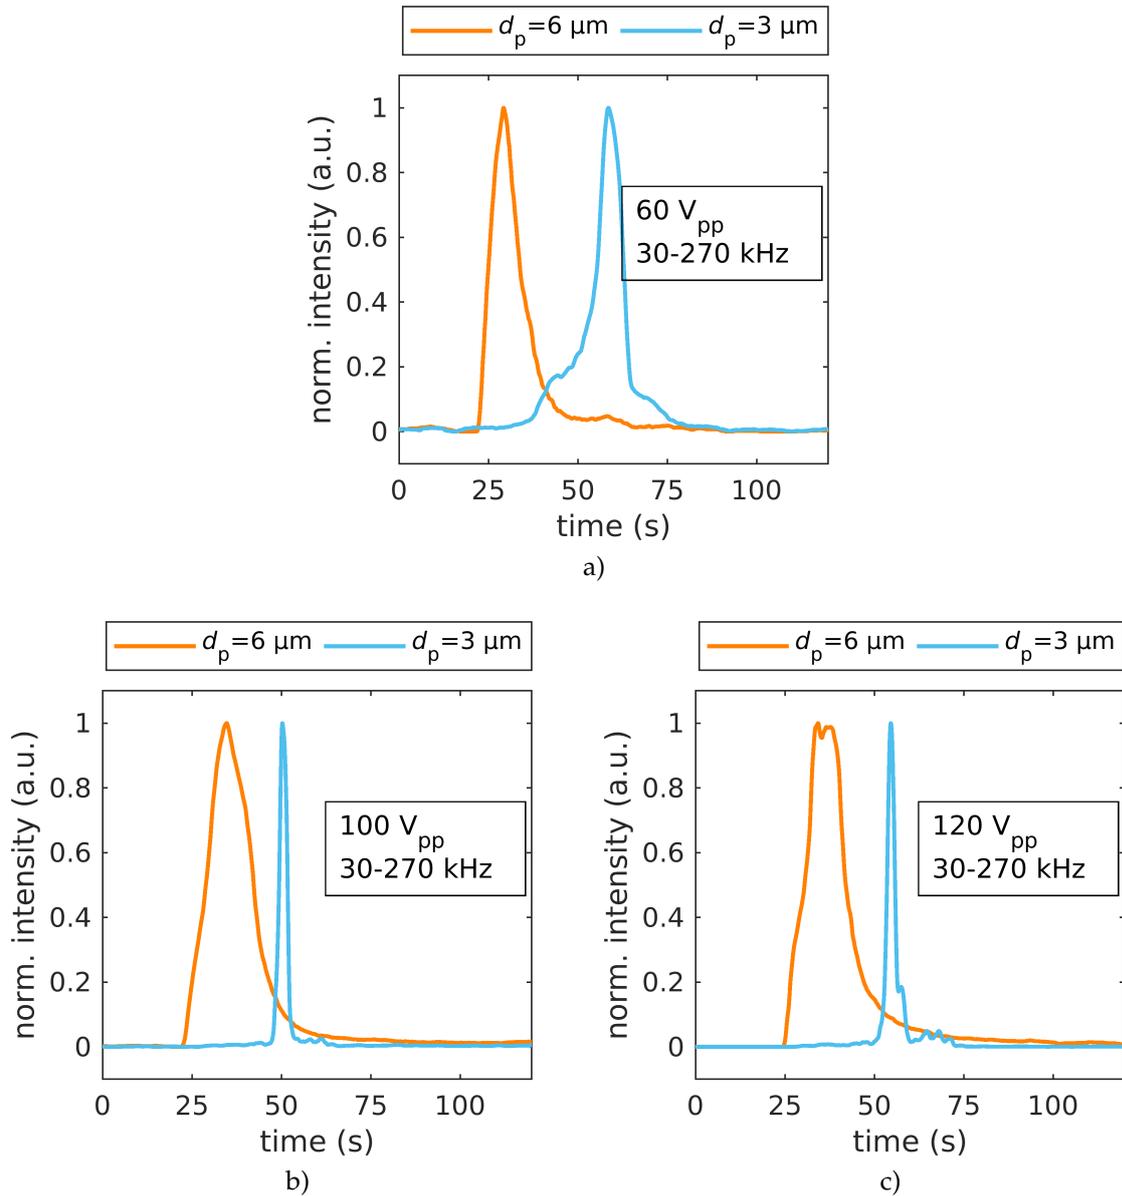

Figure 4. Fluorescence intensity over time of 3 μm and 6 μm fluorescent polystyrene particles at a) $60 V_{pp}$ b) $100 V_{pp}$ c) $120 V_{pp}$ all experiments at 30 kHz - 270 kHz with a modulation frequency of 300 mHz

37 The separation of 3 μm and 6 μm fluorescent polystyrene particles at all voltages not shown
 38 in the main manuscript is show in [Figure 4](#). For all applied voltages almost no retardation of the
 39 6 μm particles could be observed, whereas for 3 μm the residence time diverges significantly from
 40 experiments without applied voltage. According to our calculations this separation is due to the
 41 retardation of the 3 μm particles, whose behaviour is dominated by pDEP.

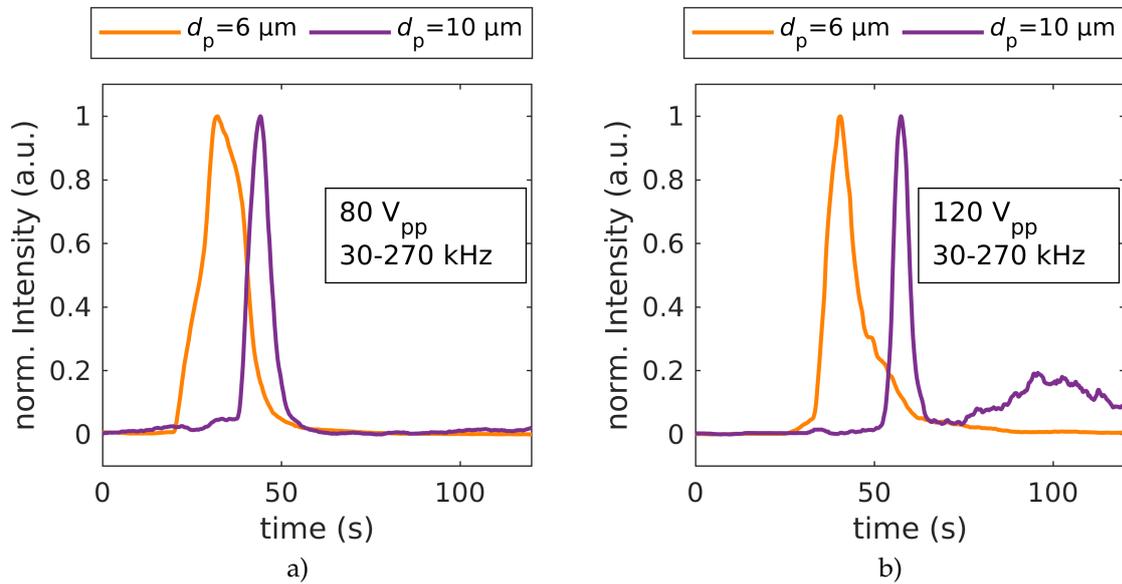

42 4.1.2. Separation of 6 and 10 μm particles

Figure 5. Fluorescence intensity over time of 6 μm and 10 μm fluorescent polystyrene particles at a) $80 V_{pp}$ and b) $120 V_{pp}$ all experiments at 30 kHz - 270 kHz with a modulation frequency of 300 mHz

43 To investigate the retention time of particles, which show, according to literature, substantial more
 44 nDEP than pDEP, the separation of 6 μm and 10 μm was chosen. As addition to the data presented in
 45 the main document the separation at $80 V_{pp}$ and $120 V_{pp}$ is presented in [Figure 5](#).

46 4.1.3. Separation of 2 and 3 μm particles

47 The increase in resolution while increasing the applied voltage of the separation of 2 μm and 3 μm
 48 fluorescent polystyrene particles is illustrated in [Figure 8](#). With increasing voltage, the width decreases
 49 and the peak maxima diverge progressively.

50 The variation of the set of frequencies (30 kHz - 270 kHz vs. 80 kHz - 320 kHz) is illustrated in
 51 [Figure 7](#) for $160 V_{pp}$. The decrease in smaller retention time using 80 kHz - 320 kHz is shown in [Figure 6](#).
 52 The particles elute significantly later, when 30 kHz - 270 kHz are applied. The higher reetention time,
 53 when using 30 kHz to 270 kHz, is due to less negative dielectrophoretic movement. Therefore, the
 54 particles are more likley to stay in areas near to the electrode in which only low fluid velocity is present.

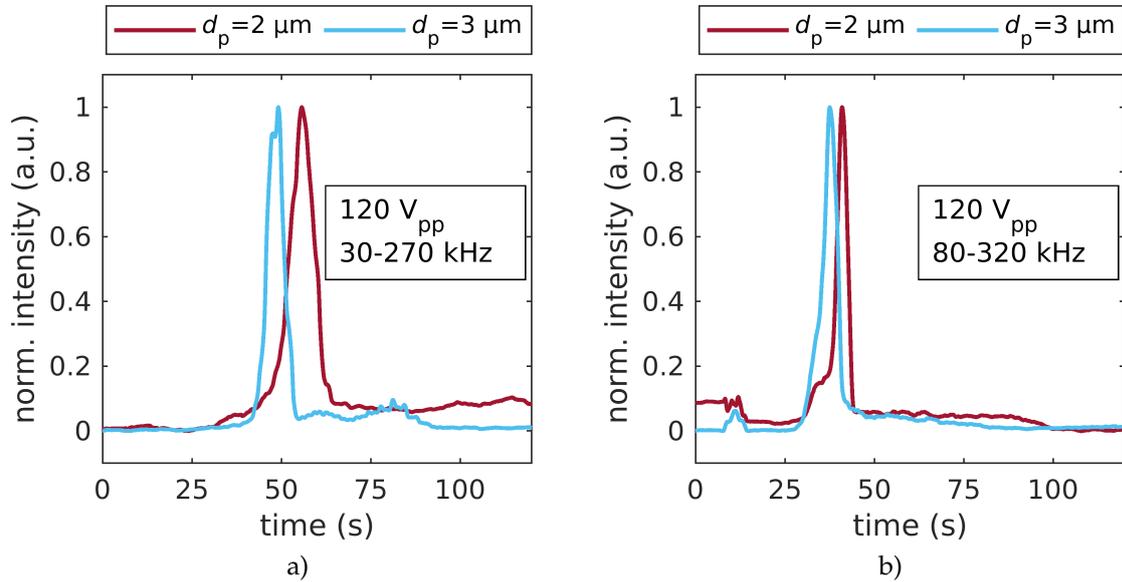

Figure 6. Fluorescence intensity over time of $2 \mu\text{m}$ and $3 \mu\text{m}$ fluorescent polystyrene particles. a) $120 V_{pp}$ at 30 kHz - 270 kHz b) $120 V_{pp}$ at 80 kHz - 320 kHz with a modulation frequency of 300 MHz

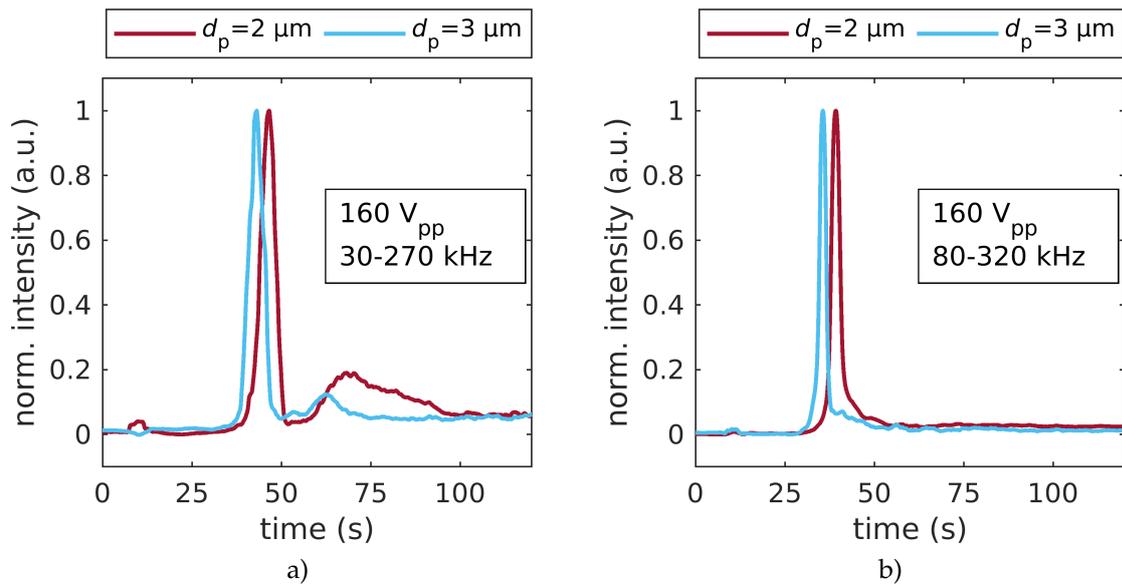

Figure 7. Fluorescence intensity over time of $2 \mu\text{m}$ and $3 \mu\text{m}$ fluorescent polystyrene particles. a) $160 V_{pp}$ at 30 kHz - 270 kHz b) $160 V_{pp}$ at 80 kHz - 320 kHz with a modulation frequency of 300 MHz

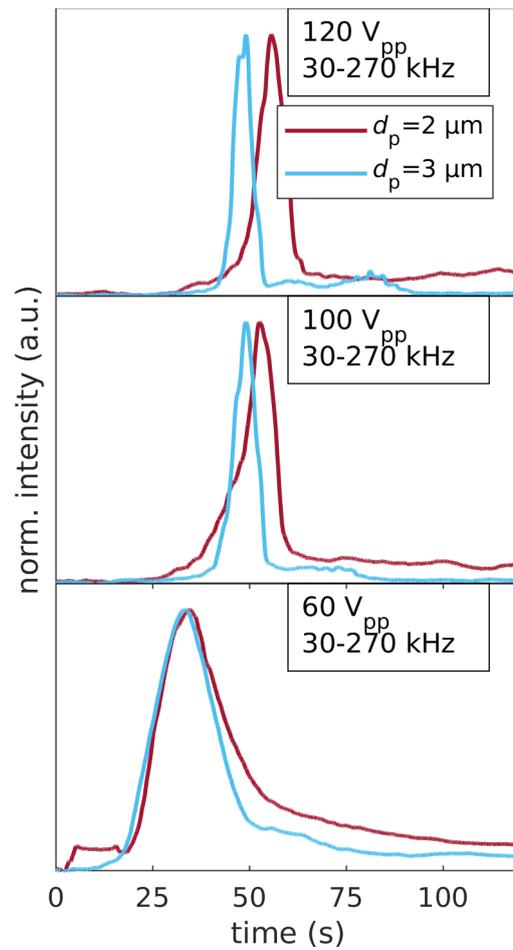

Figure 8. Fluorescence intensity over time of 2 μm and 3 μm fluorescent polystyrene particles with using different voltages. With increasing voltage the separation resolution R_s increases from $R_s(60 \text{ V}_{pp}) = 0.051 \pm 0.14$ to $R_s(100 \text{ V}_{pp}) = 0.24 \pm 0.07$ and finally to $R_s(120 \text{ V}_{pp}) = 0.54 \pm 0.1$ ($N = 4$ experiments)

55 4.2. Videos of separation and PIV data

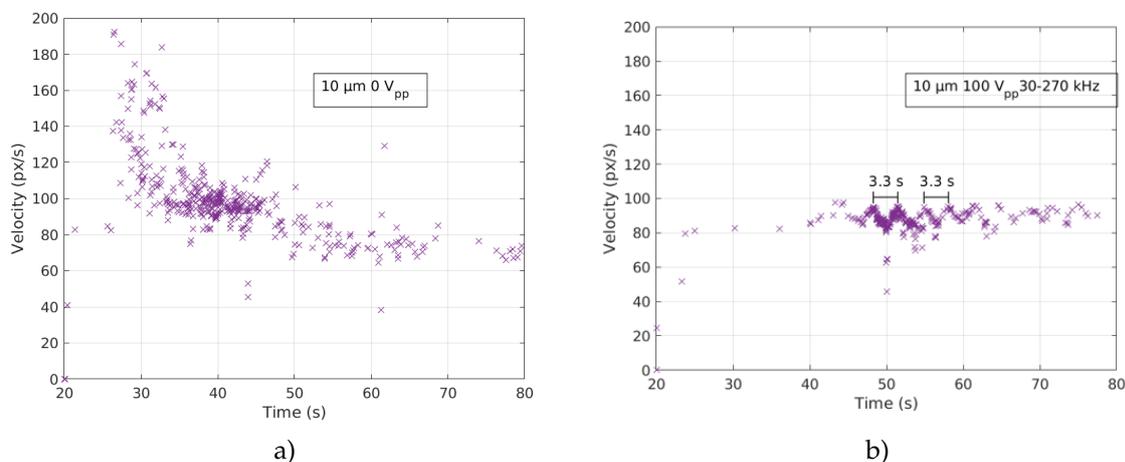

56 4.2.1. PIV of 10 μm particles

Figure 9. PIV Data of 10 μm PS particles at a) 0 V_{pp} and b) 100 V_{pp} at 30 to 270 kHz with a modulation frequency of 300 mHz. The measurement was performed at the outlet of the DPC channel, where no electrodes are present.

57 We conducted experiments with 10 μm at 0 V_{pp} and 100 V_{pp} to perform PIV measurements
 58 utilizing ImageJ and the TrackMate algorithm (s. [Figure 9](#)).

59 Without applying an electric field, at first fast particles arrive, whereas with increasing time slower
 60 particle elute from the channel. This is due to the laminar flow profile of the microchannel. When
 61 a voltage is applied, the velocity becomes more homogeneous and slower. The particles elute later
 62 from the channel and their velocity fluctuates with a 3.3 s period, which again is the cycle length of the
 63 frequency modulation. The fluctuation has an peak to peak value of about 15 px/s (80 to 95 px/s). The
 64 measurements were conducted at the outlet of the channel close to the last electrode the particles pass
 65 in the channel. No such periodic velocity change was observable for the 6 μm particles (which were still
 66 big enough to perform PIV measurements). We have also added a video "10um_100Vpp_PIVdata.mp4"
 67 to the Supplement from which the PIV data was evaluated. However, the periodic velocity changes
 68 are too small to observe them with the bare eye.

69 4.2.2. Videos for 3 μm and 6 μm particles

70 For smaller particles no PIV measurements were possible, due to their low fluorescence intensity.
 71 However, videos (0 V_{pp}: "DPC_0Vpp_3vs6umPS.mp4" & 80 V_{pp}: "DPC_80Vpp_3vs6umPS.mp4") are
 72 available as Supporting Documents of the separation of 3 and 6 μm particles with subtitles in it to guide
 73 the eye. The videos are cropped and adjusted in contrast, colour and brightness for better visibility.
 74 For future work a more powerful light source/laser could be used to generate a more detailed set of
 75 PIV data. These videos clearly show how the 3 μm particles slow down in intervals that match the
 76 applied frequency modulation. The videos were taken at the outlet of the channel close to the last
 77 electrode the particles pass in the channel.
