Abstract: This study attempts to assess the impact of corruption on economic growth in the Mediterranean countries, during the period from 1998 to 2007. Econometric analysis using panel regression has been adopted to test this effect. Individual effects models such as random effects model and fixed effects model were applied to the study sample of 160 observations, and to choose the suitable model, we implemented several tests. For our analysis, we used a basic model that includes the dependent variable GDP per capita as a factor of economic growth and the corruption perception index as the independent variable concerned. Then we completed the model with several standardized macroeconomic control variables mentioned above and applied the individual effects models. The outcomes illustrate that corruption has a negative impact on the selected Mediterranean countries' economic growth.

Keywords: Corruption; Economic growth; Panel Data

JEL Classification: C23; D73; O47

1. Introduction

In recent decades, corruption is the subject of several theoretical and empirical researchers to elucidate the relationship between it and economic growth and also the implantation of effective mechanisms against this phenomenon. Several initiatives have been taken by various international organizations like the World Bank, the International Monetary Fund, and the United Nations Development Program, to eradicate this paradox. Non-governmental agencies are established, as part of national or international strategies, to strengthen public institutions and the establishment of political regimes.

Corruption can take many forms and especially the groups of standards and customs accepted by the elites and the population (A.J. Heidenheimer et al., 1989, Y. Mény, 1992, R. Shamasastri, 2010). In this case, corruption becomes invisible and transparent. This ambiguity surrounding corruption leaves it without a precise definition. One of the accepted definitions is « the abuse of the power and the public influence for private purposes.»

The opinions about the relationship between corruption and economic growth are contradictory. As Toke S. Aidt (2009) puts it, the greasers and the sanders populate the world. The sanders believe that bribery hinder economic growth, while the greasers defend the idea that corruption can grease the wheels of the industrial machine thus help faster growth.

Corruption is a phenomenon that affects the Mediterranean region. According to Transparency International, corruption is widespread in more than sixteen countries of the Mediterranean region, and the average level of corruption in the area is far from honorable. Several large-scale extortions have recently emerged on the press, especially in Nord Africa, pointing to the ubiquity of the phenomenon.

The resurgence of the demonstrations, condemning the corruption of the elites in the countries of North Africa and the Balkans, led us to conduct this research which attempts to determine the effect of corruption on economic growth, using a panel data of sixteen Mediterranean's countries for a span of 10 years, from 1998 to 2007.

2. Literature review

The grease and the sand hypotheses dominate the debate on the effects of corruption on economic growth. Grease the wheels hypothesis, introduced by Nathaniel H. Leff (1964) and later adopted by other scholars (Raul A. Barreto, 2000, S.P. Huntington, 2006, Joseph Nye, 1967, Thierry Verdier and Daron Acemoglu, 2000), considers the explicit or total moralization, by intellectual and politicians, an obstacle to the rational analysis of the effects of corruption. Nathaniel H. Leff (1964) argued that in underdeveloped countries and precisely in the former colonies, the traditional elite that makes up the government may be hostile to economic development. The emergence of a new center of power, the middle class, can challenge conventional power holders. This puts into question the idea that the government in underdeveloped countries intelligently and actively works to promote economic development.

It has been argued that corruption is less detrimental in countries where bureaucracy is inefficient, and it can serve as an inducement for civil servants. A nation with an inflexible, too centralized and dishonest bureaucracy wants better than a country with a stiff, over-centralized and honest administration. In traditional societies, where traditional norms are sacred, a certain amount of corruption can lubricate the path of modernization. In a declining community, where corruption is pervasive, more crime is not able to improve anything.

Using a sample divided into two equal subsets, which allow discrimination between developed and developing countries, Pierre-Guillaume Méon and Laurent Weill (2010) found that in a few countries in the sample where regulation is burdensome, corruption could lead to more efficiency. Today, many developing countries are compelled to cut public spending in case the problems of the balance of payment. This implies that real pay of civil servants is reduced or remains stagnant more than those in the private sector. Such a situation fuels corruption in developing countries. In this case, fraud can bring more quality and improvement among civil servants.

To explain the enormous corruption and rapid growth in China Yuanyuan Wang and Jing You (2012) found that corruption is likely to contribute to business growth. Or where the financial markets are undeveloped, corruption seems to be vital for rapid business growth. Such increase will be observed when financial markets are well functioning, and crime is under control.

Alternatively, the sanders argue that corruption hinder the economic development. Using cross-section data, Paolo Mauro (1995) found that bribery hurts economic growth and that education in developing countries is the most affected field. When the political elite is corrupted, the government invests less in tuition. Pak Hung Mo (2001) studies the effect of corruption on the use of multiple channels of transmission. Political instability is the essential channel that affects economic growth.

In a study of Ugandan companies, researchers have shown that in the short term corruption affects economic growth in a negative way. Toke S. Aidt (2009) argue that corruption can be harmful to economic growth in long-run but in the short-run bribery can be a good greaser for economic growth. In countries where crime is not organized as a network, bureaucrats fix bribes while ignoring the negative externalities of the latter. The presence of an organized corruption network makes bribe payments lower, while economic growth and innovation are very high by the case in which this system is absent.

Because of the lack of research on investigating the relationship between corruption and economic growth in Mediterranean countries, this paper will examine this matter. Even if the Mediterranean nations differ significantly between them, they share even more common points, historical and geographical (Daniel Treisman, 2000), than differences

3. Model and data

There is no consensual theoretical framework to guide empirical work on growth and corruption, and existing models do not adequately specify the variables that must be kept constant while statistical inference on the relationship between growth And variables of interest (Table 1.).

Table 1. Definition of variables and data sources

Variables	Explanations of Variables	Data Source
FDI	FOREIGN DIRECT INVESTMENT (Griffin & Pustay, 2007)	World Bank, WDI
CPI	Corruption Perception Index	Transparency International
INFL	Inflation as measured by the annual growth rate of the GDP implicit deflator	World Bank, WDI
HC	Human capital is represented here by the percentage of population ages 25 and over that attained or completed short-cycle tertiary education.	World Bank, WDI
INV	Public investment	World Bank, WDI
TRAD	Merchandise trade	World Bank, WDI
POP	Total population	World Bank, WDI
OPEN	Economy's openness (P.R. Krugman et al., 2017)	World Bank, WDI

To test empirically the primary assumption of a link between corruption and economic growth a database of 16 Mediterranean countries was constructed for the period 1998-2007. The countries concerned are Albania, Algeria, Croatia, Cyprus, Egypt, France, Greece, Israel, Italy, Malta, Morocco, Slovenia, Spain, Syria, Tunisia, and Turkey.

Table 2. Descriptive statistics

	GDP	HC	CPI	INFL	INV	TRAD	POP	OPEN	FDI
Mean	11407.66	37.87082	4.703500	6.179553	24.95200	54.96092	25864057	75.80851	8.37E+09
Median	10090.82	31.58014	4.650000	3.378723	25.60500	46.98524	13377132	64.46087	1.11E+09

To see if the results of previous research are compatible with the recent data, we collected a balanced panel data, extracted from the World Bank database, composed of several variables already studied in the previous research. A Panel data is more efficient than cross-sections and time series.

The model in panel data can be expressed for N individuals and T temporal observations in the following way:

$$y_{it} = \alpha_{it}^{*} + \beta_t'x_{it}' + \mu_{it} \quad ,$$

(1)

where y_{it} is the dependent variable, α_{it} and $\beta'_{it}=(\beta_{1it},\beta_{2it},...,\beta_{kit})$ are 1×1 and $1\times k$ constants vectors which vary through i and t , respectively, $x'_{it}=(x_{1it},...,x_{kit})$ is a $1\times k$ vector of observations on the explanatory variables, and μ_{it} is the error term, $t=1,...,T$; $i=1,...,N$.

Our econometric model is as follows:

$$GDP_{it} = \beta_0 + \beta_1 FDI_{it} + \beta_2 CPI_{it} + \beta_3 INFL_{it} + \beta_4 HC_{it} + \beta_5 INV_{it} + \beta_6 OPEN_{it} + \beta_7 POP_{it} + \beta_8 TRAD_{it} + \mu_{it} \quad (2)$$

Table 3. Correlation analysis

4. Empirical Analysis

According to the sequential test procedure proposed by C. Hsiao (2014) we are faced with a model with individual effects. The stationarity test proposed by Andrew Levin et al. (2002) indicates that the series is stationary.

Table 4. UNIT ROOT TEST

Variable	Coefficient	t-ratio	Prob.
FDI	-1.058	-12.961	0.0000

The Breusch-Pagan test (Breusch-Pagan Lagrangian Multiplier Test) is used to determine whether the stacked MCO model is adequate by comparison to the fixed-effect model. The test hypothesis is as follows:

$$, H_0 : \sigma^2_{\lambda} = 0 \text{ against } H_1 : \sigma^2_{\lambda} > 0 \tag{3}$$

The Breusch-Pagan test statistic of our model is:

$$, LM = \frac{NT}{2(T-1)} \left[\frac{\sum_{i=1}^N (\sum_{t=1}^T \hat{\varepsilon}_{it})^2}{\sum_{i=1}^N \sum_{t=1}^T \hat{\varepsilon}_{it}^2} - 1 \right] = 452,858 \quad (4)$$

with a value of p

$$p = \text{prob}(\text{Khi-deux}(1) > 452,858) = 1,7223\text{e-}100, \quad (5)$$

The value of p is less than 0.05, which is in contrast to the null hypothesis according to which the stacked OLS model is adequate, in contrast to the alternative of the random effects.

Table 5. Correlated Random Effects - Hausman Test

Test Summary	Chi-Sq. Statistic	Chi-Sq. d.f.	Prob.
Cross-section random	41.353139	8	0.0000

The p-value of the test is less than 5%, indicating that the random effects model is not appropriate and that the specification of the fixed effects is the most appropriate.

After this brief comparison between the three models, now we are passing to the verification of our model with fixed effects between the entities. From the results of the fixed-effect regression, we will perform a redundancy test between the entities.

Table 6. Redundant Fixed Effects Tests (Test cross-section fixed effects)

Effects Test	Statistic	d.f.	Prob.
Cross-section F	103.509560	(15,136)	0.0000
Cross-section Chi-square	403.044141	15	0.0000

The two tests (cross-section F and cross-section Chi-square) evaluate the joint significance of the cross-section effects using the sums of squares (F-test) and the likelihood function square). The corresponding restricted specification is that in which periodic fixed effects are not permitted. The two statistical values (103,50 and 403,04) and the associated p-value strongly reject the null hypothesis that section effects are redundant. The fixed effects model is the right choice for this study.

Just as fixed effects for each entity can control variables that are constant over time but differ between entities, fixed time effects can control variables that are constant across entities, but they change over time.

The Schwarz criterion obtained in the periodic fixed effects model is compared with the fixed transverse effects model. The value of the periodic fixed effects model is higher than that got in the fixed effects model by sections (-0.50 < 1.72).

If some omitted variables are constant over time, but vary by the state while others are constant across countries, but change over time, then it is appropriate to include both entity and time effects.

Table 7. Redundant Fixed Effects Tests (Test cross-section and period fixed effects)

Effects Test	Statistic	d.f.	Prob.
Cross-section F	223.217097	(15,127)	0.0000
Cross-section Chi-square	529.477835	15	0.0000
Period F	20.776409	(9,127)	0.0000
Period Chi-square	144.826665	9	0.0000
Cross-Section/Period F	157.151110	(24,127)	0.0000
Cross-Section/Period Chi-square	547.870806	24	0.0000

There are three sets of tests. The first series consists of two tests that evaluate the joint significance of cross-sectional effects using sums of squares (F-test) and the likelihood function (Chi square test).

The corresponding restricted specification is one in which there are period effects only. The two statistical values (223.21 and 529.477) and associated p values strongly reject the null hypothesis that section effects are redundant. Two other tests are used to evaluate the importance of periodic dummies in the unrestricted model against a restricted specification in which there are only cross-sectional effects. Both forms of statistics firmly reject the null hypothesis of absence of period effects.

The last two tests evaluate respectively the ordinary meaning of all the effects. Both test statistics reject the restricted model in which there is only one intercept. The test results indicate that the cross-sectional and periodic fixed effects model is the most appropriate.

Finally, we are going to verify of the residual. It is commonly accepted that disturbances in panel data models are cross-sectioned independently, especially when the transverse dimension (N) is large. There is, however, considerable evidence that cross-sectional dependence is often present in regression parameters with panel data.

The ignorance of addition in cross section in the estimate can have serious consequences, with unaccounted for residual dependence resulting in a loss of efficiency of the estimator and false test statistics.

The Pesaran CD test is based on the average pairwise correlation coefficients

$$\rho_{ij} : CD_p = \sqrt{\frac{2}{N(N-1)}} \sum_{i=1}^{N-1} \sum_{j=i+1}^N T_{ij} \rho_{ij} \rightarrow N(0,1), \quad (6)$$

which is asymptotically normal for $T_{ij} \rightarrow \infty$ and $N \rightarrow \infty$ in any order.

We will use this test because T is relatively small and the test is likely to have good properties for both N and T of small dimensions (B. Baltagi, 2008).

The null hypothesis is that there is no cross-sectional correlation in the residues. The value of the statistical test is -0.92 and the value of p = 0.3572 is greater than 5%. The null hypothesis that there is no cross-sectional correlation in the residues is accepted. To obtain a robust model, we will use the method of the white diagonal (C. Hsiao, 2014).

5. Discussion

Paolo Mauro (1995) in his treatise on Nathaniel H. Leff (1964) on the relationship between growth and investment with corruption, finds that corruption negatively affects economic growth. Paolo Mauro (1995) thinks that being corrupt, unstable governments spend less on education. This finding is consistent with the suggestion made by other researchers that opportunities for corruption may be less abundant on education than on other components of government spending. The empirical results suggest a partial explanation for the stylized fact that developing countries tend to have burdensome and corrupt bureaucracies, and to be politically unstable (Paolo Mauro, 1995). Since institutional inefficiency persists over time, corrupt institutions in the past may have played a significant role in achieving low economic growth, leading to poverty today.

From a sample of African countries during the 1990s and using a dynamic panel data estimator, Kwabena Gyimah-Brempong (2002) studied the effects of corruption on the rate of income growth by resident and income distribution. Using Transparency International's Corruption Perception Index, he

finds that dishonesty decreases the rate of revenue growth. An increase of one unit of the corruption index reduces the GDP growth rate from 0.75 to 0.9 percentage points and the per capita income from 0.39 to 0.41 points percentage (a proportionately large effect given Africa's weak economic growth). Corruption decreases the per capita income growth rate directly by reducing the productivity of existing resources and indirectly by reducing investments. Kwabena Gyimah-Brempong (2002) finds that, given the level of corruption and other factors, if the level of consumption is high, per capita income growth will slow down. In addition to the slowdown in the per capita income growth rate, corruption is also associated with high-income inequality in African countries suggesting that the poor bear the brunt of the economic effects of crime in African countries.

The results of this study, conducted by Kwabena Gyimah-Brempong (2002), suggest that increasing the well-being of the majority of citizens in African countries can be improved by reducing corruption. This means that the process of economic development can be achieved using domestic resources without recourse to seeking outside help. After all, the effect of external growth aid is less than the impact of corruption on growth. Instead of African countries asking for foreign aid to boost economic development, they could achieve the desired financial performance by reducing bribery through appropriate institutional reforms. These institutional changes will lead to sustained economic growth in the long term. The results of this study should, however, be interpreted with caution.

Toke S. Aidt (2009) finds that while corruption in a narrow sense can be seen as a greaser that can speed things up and help entrepreneurs to create wealth, in a broader sense corruption should be seen as an obstacle to economic development in the future long term.

The results of the previous research indicate that corruption can be a greaser for the economy only in times of economic transition. The misleading aspect of the effectiveness of corruption is another reason. The burdensome policies that crime is supposed to help overcome can be created and maintained precisely because of their potential for fraud, and substantial real resources can be spent on challenging the associated rents. This leads to pure waste and misallocation of resources. There is also inconsistency of hiding composition. Undisputed but isolated cases of corruption, improving efficiency at the micro level cannot be considered as evidence that corruption can increase macroeconomic efficiency.

Several pieces of evidence support this point of view. Quantitative data from studies and field surveys highlight the high costs of corruption. At the macroeconomic level, although the search for an adverse effect of fraud on the average growth rate of GDP per capita has not given conclusive and consistent evidence, this does not mean that crime is irrelevant at this level. At least in a society with good governance and strong political institutions, corruption reduces growth at the margin. More importantly, even though the average effect of corruption on GDP growth is close to zero, the new evidence presented above suggests that crime is a significant obstacle to sustainable development. No doubt, I barely scratched the surface. Much more work is needed to establish the robustness and causality of the correlation between corruption, and the rate of real wealth per capita is growth and build better measures of real wealth. Nevertheless, as some research rightly points out, we should be shifting our attention from per capita GDP growth to true wealth growth and start asking questions about what economic, political and legal institutions play in promoting the accumulation of real wealth and sustainable development.

From the empirical results, a significant finding has been discovered. At a confidence interval of 95% and in our fixed-effects models, corruption negatively affects economic growth in the countries of the

Mediterranean. This is the conclusion throughout the literature, as previously established, and, besides, also from the results in the data set of this document. But these results must be interpreted with caution. The index we used here is based on perception. This index does not specify whether corruption is organized or not, centralized or decentralized and whether it involves senior officials or not. This can affect the size of the losses brought by bribery. It should also be noted that the sample used for memory is too small to deduce a general trend. For these reasons, the results presented here should be considered indicative.

6. Conclusion

The study of corruption needs a precise definition of the phenomenon. According to Transparency International, the civil society organization dedicated to transparency and honesty in public and economic life, corruption is the abuse of delegated authority for private purposes. More specifically, corruption occurs when a briber secretly gives favor to a corrupt or a candidate to influence the action (s) that benefit the briber or a nominee, and for whom the evil has authority (IAN SENIOR, 2004). It is characterized by its elasticity, the ability to take the most family-friendly forms of norms and customs accepted by elites and by the population and its vulnerability to the combination of democracy and freedom of the press (Christine Kalenborn and Christian Lessmann, 2013).

As part of this work, we have tried to participate in the resolution of the following fundamental question: Does corruption fat the wheels of the economic machine or does it hinder the machinery of the economic engine?

To do this, we used a cylindrical set of panel data composed of 16 countries in the Mediterranean region for the period from 1998 to 2007. The empirical results of this work, obtained through fixed-effect models, reinforce the conclusion reached by previous empirical research in this area, especially that of Paolo Mauro (1995) and Toke S. Aidt (2009), which stipulated that the influence exerted by corruption on economic growth is negative. A culture in common can explain the strong presence of corruption in the countries of the Balkan region and the Middle East and North Africa (Martin Paldam, 2002). On the other hand, education and investment have a positive effect on economic growth. In developing countries, education has a direct and positive influence on economic growth (Masakazu Hojo, 2003).

It can be concluded, though not confirmed, that this work has allowed us to partially show the existence of a relationship between corruption and economic growth and to take into account, to a certain extent, historical and geographical effects in the relationship between economic growth and corruption.

Appropriate institutional reforms, the strengthening of the rule of law and the abolition of natural laws, created by cultural values, can lead to sustained long-term economic growth and stability in most Balkan countries and the Middle East and North Africa region.
